## **1.0 INTRODUCTION**

This report presents the findings of a water budget analysis that was completed for the Wildacres Resort portion of the proposed Belleayre Resort at Catskill Park. The work was performed by Alpha Geoscience (Alpha) for Crossroads Ventures, L.L.C (Crossroads) as part of their assessment of potential environmental impacts associated with development of this portion of the overall project site. The Wildacres Resort project area is shown on Figure 1 and contains the proposed Wildacres hotel with Conference Center and Spa, octoplex units and their clubhouse, the Highmount Golf Club 18-hole course, and the 21-lot private home subdivision that will be known as the Highmount Estates.

The area covered by the water budget analysis is approximately 723 acres. The water budget area includes the project area, as well as the roads passing through the project area. The majority of that proposed development area is within the drainage basin that contains the water supplies for the Village of Fleischmanns. These water supplies, which consist of wells and springs, are downgradient of the project area and are being considered as the primary source of irrigation and potable water for the Wildacres Resort.

NYSDOH records indicate that Fleischmanns currently has a daily water usage of between 190,000 gpd and 300,000 gallons per day (gpd), depending on seasonal variation. A community the size of Fleischmans is expected to use 80,000 gpd to 90,000 gpd, based on population and assuming a 20% to 30% leakage (DEIS, Section 3.9.3). This indicates that the current Fleischmans water distribution system is losing 100,000 gpd to 220,000 gpd to leakage. The Village recently identified and repaired a number of leaks resulting in a decrease in water use of 185,000 gpd. The current demand of the estimated 351 users of the Village of Fleischmanns is 40,000 gpd. Since this reduction is very recent and long term demand figures are not available, the analysis in this report uses the worst case, more conservative, former demand for the Village. Alpha Geoscience evaluated the Fleischmanns water supply in 2000 (Alpha Geoscience, 2000) and again in 2002 (Alpha Geoscience, 2002). The existing water capacity of the Fleischmanns wells and springs is approximately 573,120 gpd, as determined for the drought conditions of 2001.

Alpha examined the potential effect that direct withdrawal by the Wildacres development might have on those resources (Alpha Geoscience, 2002). That examination revealed that direct withdrawal from the Fleischmanns water supply (as it currently exists, or from a proposed new well) to meet the Wildacres peak total flows for potable and irrigation water (250,560 gpd during the summer) would still leave Fleischmanns with a substantial excess capacity (Alpha Geoscience, 2002).

The purpose of the water budget analysis was to estimate the total quantitative change in the ground water resources affected by the Wildacres Resort project development. This was accomplished by first evaluating the amount of infiltration to the ground water system under existing conditions and then estimating the change in total infiltration that will be brought about as the result of the post-development conditions. The water budget provides a mechanism of estimating infiltration by balancing the amount of precipitation with runoff, percolation to the subsurface and evapotranspiration (evaporation of the ground surface and transpiration by plants). This balance is dependent on those factors such as vegetation cover, soil type and land use, which will change when development occurs. The change from the pre-development (existing conditions) to the post-development (peak development conditions) infiltration rates was estimated to assess impacts by factoring in modifications to the land by development. The amount of infiltration to the ground water system is the source of the Fleischmanns ground water supply. The estimated change in infiltration rates for the future conditions was used to assess the potential impacts to the Fleischmanns water supply resources.

## **2.0 METHODS**

### **2.1 Existing Conditions**

The areas that were analyzed for the existing conditions water budget correspond to the mapped soil areas within the project area as provided in the DEIS Section 3.6 and Appendix 12, "Soil Test Results". Plates 1 and 2 show the existing soil types and the mapped soil units throughout the entire Wildacres Resort project area. Each of the soil map units was numbered for identification and tracking purposes. Due to the large amount of open area in the western part of the project area, soil

map units containing both wooded and non-wooded areas were subdivided. The numbering scheme on the existing conditions soils map reflects these subdivisions (e.g., 141 VhD is subdivided into 141-1 VhD and 141-2 VhD). Each of the numbered map units is listed in Appendix A with their corresponding soil type and calculated area. The areas for each of the mapped units of the same soil type and forest cover (wooded or non-wooded), were then summed to arrive at a total area within the project site (Appendix A).

Water budget analyses were then completed for each soil type, both wooded and non-wooded, based on climatic data from the Slide Mountain Station (NOAA Station ID 307799) and on specific soil properties presented in the DEIS Appendix 12, "Soil Test Results", and the Soil Survey of Greene County, New York (USDA, 1993). The Slide Mt. weather station is the closest weather station to the project area with a thirty-year record of temperature and precipitation. Precipitation at the Slide Mountain station is likely to be more similar to the project area than any other NOAA station due to its proximity, comparable elevation and its similar physiographic setting. It is located 8.7 miles south-southeast of Pine Hill and at an elevation of 2649 feet AMSL. The vast majority of the Wildacres project area is situated above 2000 feet AMSL.

Information on physical properties of the soils was obtained from neighboring Greene County soil survey because the Ulster County soil survey is out of date and the Delaware County soil survey with modern soil classifications has not yet been published. The soil type classifications presented in the DEIS Appendix 12 represent the modern classifications of the soils within the water budget area, therefore, the physical properties of the soil types can be obtained from any of the modern published soil surveys (See DEIS Section 3.6, "Soils" for more information).

The water budget analysis for each soil type within the project is summarized in Appendices B1 and B2 for wooded and non-wooded areas, respectively. Some soil types (e.g., VhC, VhD, and VhF) were analyzed together for the water budget based on their similar soil properties.

## **2.2 Post-Development Conditions**

The entire area to be developed was subdivided into the following four different categories for water budget purposes: the Wildacres Resort grounds (areas W1 through W6), the golf course (areas G1 through G5), the ponds (areas P1 through P2), and Highmount Estates (H1). The Wildacres Resort grounds contain all the roads, buildings, sidewalks and landscaping that comprise the Resort, maintenance and service buildings, and the waste water treatment plant (WWTP). The golf course areas include the driving range and all tees, greens and fairways, exclusive of the ponds. The areas of the proposed golf course, ponds, and Resort grounds of the eastern project area are all shown on Plate 3. The Highmount Estates area, shown on Plate 4, includes the proposed subdivision roads, cul-de-sacs, and the proposed area to be cleared and graded.

The total area of land within the water budget area that will have changes in the soil properties for water budget purposes is approximately 204 acres. This area is shown on Plates 3 and 4, which are keyed to Table 1. The remaining 519 acres within the water budget area will remain largely undeveloped; consequently, that acreage will retain the soil properties that currently exist. Many of these undeveloped areas appear on Plate 4 as isolated remnants of the existing forest cover. Soil properties were assigned to each of the proposed areas to be developed based on proposed land use. The total area for each of the four categories of development was calculated, as was the total area of pavement (roads, sidewalks, tennis courts), buildings and non-wooded (grassy) areas within each area (Table 1).

The future, undeveloped area comprises the majority of the acreage within the project area. The total area for each soil type that will not be developed was determined for the post development phase and is listed in Appendix C. Some of the numbered soil map units for the existing conditions are expected to be truncated, subdivided, or eliminated by the proposed development of the Wildacres Resort grounds, golf course, ponds and Highmount Estates. The numbering scheme used for the existing conditions soil map units is retained in the future conditions maps (Plates 4 and 5), with additional

letters where necessary to reflect subdivisions of a particular map unit (e.g., 100-1 HvF is subdivided into 100-1A HvF and 100-1B HvF). Most of the soil map units in the west area of the project are not expected to have any change in total area since little development other than Highmount Estates has been proposed there. The boundaries of those soil areas that are expected to change due to the proposed Highmount Estates development are highlighted with bold emphasis on Plate 4. Plate 5 shows the undeveloped soil areas that will remain in the eastern half of the project area after development of the golf course, ponds and hotel grounds. The soil map unit areas for the future conditions are included in Appendix C.

The water budgets for the existing and future conditions are the same for the soil types in the areas not to be developed (Appendices B1 and B2). Water budget analyses for the future conditions within each of the proposed development areas are summarized in Appendix D and were completed based on climatic data and estimated soil properties determined from land use. Several other key assumptions for the future, post-development, water budget analyses are presented in the following bullets:

- A weighted average approach was used to determine a runoff coefficient (CR) for each of the Wildacres Resort development areas (W1 through W6). The total areas of buildings (roof areas), pavement (roads, sidewalks, tennis courts), and non-wooded (grassy) areas were calculated for each area (Table 1). Runoff coefficients were then determined for each area by using published CR values in a weighted average.
- Soil moisture for each of the Wildacres development areas (W1 through W6) was determined by averaging the soil moisture for the existing soil types within each of the proposed development areas.
- The runoff coefficient and soil moisture values were determined for Highmount Estates (H1) in the same manner as with the Wildacres development areas (W1 through W6), except that the sizes and locations of the buildings (houses) that may be built in the Highmount Estates subdivision are unknown. Alpha considered the potential impacts to infiltration that the

houses may have if 21 houses were built (outside of area H1) and each house covered 4000 sq. ft. of soil area. The runoff from these buildings will drain to the soil surrounding the buildings and will have the effect of additional precipitation to the surrounding soils. This precipitation surcharge to the surrounding soils largely offsets the loss of infiltration beneath each of the houses; consequently, the resulting change in infiltration to the ground water system is expected to be negligible.

- The top soil that will be used in construction of the Highmount Country Club golf course (Areas G1 through G5) is assumed to be a sandy loam that will have an average thickness of eight inches. The average solum thickness (depth to root base) for the golf course areas (G1 through G5) is expected to be approximately twelve inches once the course has fully developed.
- All runoff from the Wildacres Resort and the golf course areas was assumed to enter the three proposed storm water detention ponds (P1, P2 and P4) and to be lost to the system (i.e., no infiltration). This approach in determining the total change in infiltration rates for the project area is conservative since, in reality, not all storm runoff will enter the detention ponds – some will percolate downward along the drainage swales and through the pond bottoms. If this added infiltration were included in the analysis, the resulting infiltration rate would be higher.
- Downward infiltration from the irrigation pond (P3) was assumed to be non-existent due to the fact that the bottom of the irrigation pond will be covered with a geotextile or a clay liner.
- Irrigation water for the golf course is assumed to originate from the Fleischmanns water supply, which is located down gradient of the project area. In order to maintain a conservative approach in estimating the potential change in infiltration to the ground water system, the positive effects of irrigation water surcharge on the golf course areas were not included in the water budget analyses for the future development areas (Appendix D). The application of irrigation water throughout the golf course, would theoretically meet the soil moisture demand of the grass within each of the golf course areas (G1 through G5); therefore, it is assumed that

the irrigation water will be completely removed from the system through evapotranspiration. However, the addition of irrigation water will actually increase the amount of infiltration to the ground water system by negating the soil moisture deficit that normally occurs during the summer months when the golf course would be in full operation. The irrigation water, in reality, will act as a precipitation surcharge with a resulting increase in infiltration throughout the golf course areas.

- The WWTP for Wildacres Resort will be designed such that the treated water can be diverted to the irrigation ponds or discharged to subsurface beds. Since the water passing through the WWTP will have been obtained from a source (Village of Fleischmanns) downgradient from and outside of the project area, WWTP discharge to the subsurface beds will be equivalent to additional recharge to the ground water system. In order to maintain a conservative approach in estimating the changes in infiltration to the ground water system, the beneficial and positive effects of WWTP subsurface discharge were not incorporated in the water budget analysis.

### **3.0 RESULTS**

#### **3.1 Existing Conditions**

The water budget analysis performed for the existing conditions indicates that the infiltration rate for the entire area covered by the water budget analysis (723 acres) is approximately 695 gallons per minute (gpm), which is equivalent to 0.96 gpm per acre. Table 2 summarizes the annual infiltration by soil type under existing conditions.

#### **3.2 Post-Development Conditions**

Table 3 summarizes the annual infiltration estimated for each of the proposed development areas and for each soil type within the future, undeveloped project area. The water budget analysis for the future, post-development conditions indicates that the infiltration rate for the entire area will be approximately 708 gpm, which is equivalent to 0.98 gpm per acre. This 0.02 gpm per acre increase in the infiltration rate with respect to existing conditions represents a gain of approximately 14.5 gpm

over the entire 723-acre water budget area. This small change in infiltration, although negligible when compared to the normal seasonal and yearly climate fluctuations, does indicate a slight increase in the ground water resources available to the area.

#### **4.0 CONCLUSIONS**

A water budget analysis was completed for an area containing the Wildacres Resort portion of the proposed Belleayre Resort at Catskill Park. The purpose of the water budget analysis was to estimate the amount of infiltration contributing to the ground water system under existing conditions and after peak development of Wildacres Resort. The results indicate that the current infiltration rate for the study area, using the existing conditions, is approximately 0.96 gpm per acre. The results of the water budget analysis completed for the future, post-development conditions indicate that infiltration to the ground water system in the area of analysis will be approximately 0.98 gpm per acre. This positive change indicates that there is a very slight increase in infiltration to the ground water after peak development of the Wildacres Resort. This slight increase equates to a gain of approximately 14.5 gpm of recharge to the ground water system from the entire 723-acre water budget area. This slight increase is due to the fact that the positive infiltration characteristics of the golf course make up for the negative infiltration characteristics of buildings and paved areas.

Golf course irrigation, WWTP subsurface discharge, and pond infiltration were considered but not incorporated into the water budget calculations. Incorporation of these factors into the analysis would further increase the amount of infiltration to the ground water system and result in more ground water resources for the area of study.

The results of this analysis indicate that the development of Wildacres Resort will not negatively impact the quantity of available water resources in the study area. Since the study area is upgradient of the Fleischmanns water supply, the water resources available to Fleischmanns will not be impacted by the development of the Resort. The direct withdrawal of water from the Village of Fleischmanns water supply, for potable and irrigation purposes, will still leave Fleischmanns with excess capacity as discussed in Alpha (2000) and Alpha (2002).

		29.67										

Average Annual Precipitation: 60.24 inches plus run-on from Rock Outcrop (29.67 inches) = 89.91 inches

Runoff : 37.76

Total AET: 20.36

Note(s):

Total Non-Wooded HrF area = 1,433,213 sq ft. , assumed to be 67% Halcott (HaC) and 33% Rock Outcrop.

Non-Wooded HaC area = 960,253 sq ft

Non-Wooded Rock Outcrop area = 472,960 sq ft

Monthly rainfall on Rock Outcrop area assumed to runoff directly to Halcott (HaC) area as additional precipitation to Halcott area

Total Percolation: 31.79

PERC+AET+RUNOFF= 89.91

Note(s):

Soil Area excludes Marlowe Mansion, which is included in Wildacres Resort area W1 for the future conditions. This soil area is essentially undeveloped, however, the total percolation is different than existing conditions due to the exclusion of the Marlowe Mansion. The effects of the building are incorporated in the runoff coefficient for W1.
